PHYSIOTHERAPY AND OCCUPATIONAL THERAPY

A Geriatric Experience in the Acute Care Hospital¹

Francesco Landi,² MD, Giuseppe Zuccalà, MD, Roberto Bernabei, MD, Alberto Cocchi, MD, Luca Manigrasso, MD, Alessia Tafani, PT, Giuliana De Angelis, PT and PierUgo Carbonin, MD

ABSTRACT Landi F, Zuccalà G, Bernabei R, Cocchi A, Manigrasso L, Tafani A, De Angelis G, Carbonin PU: Physiotherapy and occupational therapy. *Am J Phys Med Rehabil* 1997;76:38-42

The continuously growing segment of the geriatric population with the high incidence and prevalence of comorbidity and disability suggests that enhanced preventive and rehabilitative programs will be mandatory. The early arrangement of comprehensive assessment and rehabilitation services is extremely important not only in preventing the decline of patients in the acute care settings and successive prolonged care before discharge, but also in improving functional status at discharge. We have considered the effectiveness of a rehabilitation program in acute medical care of the elderly. This article discusses a pilot project being carried out at Catholic University Hospital "A. Gemelli" of Rome.

KEY WORDS: Elderly, Disability, Rehabilitation, Multidisciplinary Team

Rehabilitation Program (PT + OT therapy)

Phase	Program	Goals
Step 1. Multidimensional assessment	Evaluation of sociodemographic, neuropsychological, functional and medical areas	Identifying the problematic areas, the risk of having a problem, the rehabilitation potential
Step 2. Patients in bed	Bed positioning, active and passive exercises, bed adaptive equipment, dressing the upper body, eating independently	Restoring or preserving normal function, preventing or correcting contractures, increasing range of motion, maintaining integrity of the skin, increasing circulation, providing proprioceptive and kinesthetic stimulation
Step 3. Patients on the ward	Transferring from bed, chair or wheelchair positioning, elementary group activities, ADLs training	Increasing body alignment, improving postural control, enhancing upper extremity, preventing contractures, increasing autonomy, alleviating burden care
Step 4. Therapy gymnasium	ADL and IADL training (eating, dressing, walking, grooming, using toilet, washing, cooking, using a telephone), providing adaptive equipment	Maintaining and increasing ability in performing activities of daily living and other functional activities, increasing perceptual/cognitive skills, promoting positive self-image through purposeful activities

Journal of
Neurology

2006, 13: 17-23

Patients who suffer a stroke event are at high risk of functional decline after the post-acute rehabilitation period. The aim of the present study was the evaluation of factors associated with functional decline in a large sample of older patients with stroke living in the community. The study population consisted of all patients admitted to home care programs after a post-acute rehabilitation program – with at least 1 year of follow-up – in twenty-two Italian Home Health Agencies from 2000 to 2002 ($n = 1338$). For the present study we selected 355 (26%) patients with diagnosis of stroke. After 1 year of in-home care program, 149 out of 355 stroke survivors (42%) had presented a worsening in the activities of daily living (ADL) scale score. In the final adjusted model, patients with cognitive impairment (OR 2.59, 95% CI, 1.45–4.64), pressure ulcer (OR 2.74, 95% CI, 1.45–5.18), urinary incontinence (OR 1.64, 95% CI, 1.01–3.29), or hearing impairment (OR 1.83, 95% CI, 1.02–3.29) were more likely to significantly decline in physical functioning after a period of 1 year in-home care program. Our study documents that functional decline of stroke patients was largely dependent on specific subjects' clinical characteristics. Three of four concomitant disabling conditions associated in our sample with functional decline – pressure ulcer, urinary incontinence, hearing – can be prevented and eventually treated or modified. Appropriate post-acute rehabilitation programs and adequate home care interventions focused on the prevention and treatment of these conditions might be correlated to better outcomes in older post-stroke patients.

Predictors of Rehabilitation Outcomes in Frail Patients Treated in a Geriatric Hospital

Francesco Landi, MD, PhD, Roberto Bernabei, MD, Andrea Russo, MD, Giuseppe Zuccalà, MD, Graziano Onder, MD, Luciana Carosella, MD, Matteo Cesari, MD, and Alberto Cocchi, MD

OBJECTIVES: To evaluate the effect of medical indicators of health status on functional gain during rehabilitation of frail older patients.

DESIGN: Observational study.

SETTING: A hospital geriatric rehabilitation department (Catholic University of Rome).

PARTICIPANTS: Two hundred forty-four older patients admitted consecutively for rehabilitation after acute illnesses between March 1999 and June 2000.

Journal of the
AMERICAN GERIATRICS SOCIETY

MEASUREMENTS: Patients were evaluated with the Minimum Data Set for Post-Acute Care (MDS-PAC) assessment form soon after the admission and every 2 weeks thereafter. Two summary scales based on MDS-PAC items are designed to describe the performance in personal activities of daily living (ADLs) and the level of cognitive function (Cognitive Performance Scale). To identify predictors of functional recovery, we constructed a multiple logistic regression model having as a dependent variable the improvement of one or more points in the ADL scale.

Landi et al. JAGS 2002;50:679-684

Predictors of Rehabilitation Outcomes: A Comparison of Israeli and Italian Geriatric Post-Acute Care (PAC) Facilities Using the Minimum Data Set (MDS)

Jacob Gindis, MD, Adrian Walter-Ginzburg, Moshe Geitzen, MD, Shulamit Epstein, PhD, Shmuel Levi, MD, Francisco Lasañ, MD, PhD, and Roberto Bernabei, MD

Objectives: To understand the relative contribution of sociodemographic, clinical, and health care features to rehabilitation outcomes in Israel and in Italy in post-acute care (PAC) facilities.

Design: Prospective cross-national study

Setting: Two hospital geriatric PAC departments: Harzfeld Geriatric Hospital, Gedera, Israel, and Catholic University of Sacred Heart Geriatric Hospital, Rome, Italy.

Participants: Post-acute care patients aged 65 and older admitted consecutively for stabilization, improvement, or rehabilitation to 3 departments in Harzfeld Geriatric Hospital, Gedera, Israel from April, 1999 through February, 2002 (N = 364), and to the post-acute Geriatric Rehabilitation Unit of the "A. Gemelli" Hospital, Catholic University of Sacred Heart, Rome, Italy, between February, 1999, and April, 2002 (N = 351), for whom there were complete assessments at admission and discharge (the total number admitted in Israel was 505, and in Italy, 409).

Measurements: Minimum Data Set for Post-Acute Care (MDS-PAC) assessments conducted within 4 days of admission and at discharge; data collected identically in both sites. Predictors of functional recovery were identified using multivariate binary logistic re-

gression. The dependent variable: improvement of 1 or more points in the ADL scale.

Results: The staffing pattern of the PAC department in Italy had about double the physicians and physio- and occupational therapists than in Israel, but about the same number of nurses and somewhat fewer aides than in Israel. Multivariate binary logistic regression that includes country, age, sex, and marital status, found that the patients in Italy had about triple the probability of improvement in ADL function (OR 3.3, CI 2.4-4.6) ($P < .001$) than PAC patients in Israel. Even after health system characteristics were added to the model, ADL improvement was most significantly associated with higher cognitive ability and a diagnosis of hip fracture, as well as longer length of stay and being admitted to PAC directly from an acute hospital. For each additional point (worse cognition) in a cognitive scale, there was a 30% decrease in the probability of ADL improvement (OR 0.7, CI 0.6-0.8, $P < .001$). Those who had a stroke were about half as likely to show ADL improvement (OR 0.5, CI 0.3-0.7) than those without stroke, but those with a hip fracture had more than double the probability of ADL improvement (OR 2.7, CI 1.7-4.2) than those without hip fracture. Those who stayed in the PAC ward an additional block of time had a 30% higher probability of ADL improvement ($P < .1$), and those who were admitted directly to PAC from an acute hospital had more than 4 times

V. Strategie di intervento

- fisioterapia
- terapia occupazionale

Occupational therapy for patients with problems in activities of daily living after stroke

Background

Occupational therapy aims to help people reach their maximum level of function and independence in all aspects of daily life.

Objectives

To determine whether occupational therapy focused specifically on personal activities of daily living improves recovery for patients following stroke.

Main results

We identified 64 potentially eligible trials and included nine studies (1258 participants). Occupational therapy interventions reduced the odds of a poor outcome (Peto odds ratio 0.67 (95% confidence interval (CI) 0.51 to 0.87; $P = 0.003$), and increased personal activity of daily living scores (standardised mean difference 0.18 (95% CI 0.04 to 0.32; $P = 0.01$). For every 11 (95% CI 7 to 30) patients receiving an occupational therapy intervention to facilitate personal activities of daily living, one patient was spared a poor outcome.

Authors' conclusions

Patients who receive occupational therapy interventions are less likely to deteriorate and are more likely to be independent in their ability to perform personal activities of daily living. However, the exact nature of the occupational therapy intervention to achieve maximum benefit needs to be defined.

Geriatric Rehabilitation

F. Landi, P. U. Carbonin, and R. Bernabei

The need for preventive and rehabilitative programs is steadily increasing with the growing proportion of the elderly in the population and the associated high rate of comorbidity and disability. Modern thought holds that the philosophy of rehabilitation should be the heart and primary aim of geriatrics.

Editorial Comment

... the emerging lack of resources for health care services in industrialized nations and the increasingly limited availability of rehabilitation services point to a critical need for evidence based criteria that would determine which patients stand to benefit the most (recovery/stabilization) from specific rehabilitative programs. Further investigations are needed to define which parameters can predict the rehabilitative potential of various types of therapy that focus on physical, psychological, and social approaches, and whether the potential recovery of old subjects is influenced by different techniques (OT programs).

Geriatric Medicine: It's More Than Caring for Old People

*(...) "the defining feature of geriatric medicine is not age, but rather the intense focus on the **preservation and restoration of function**. Because optimizing function is central to persons of all age groups who are afflicted with chronic disease or disability, **many of the fundamental principles and practices of geriatric medicine are broadly applicable across disciplines and subspecialty areas**. The underlying premise of this commentary is that **geriatric medicine represents more than caring for old people; it is a mind-set, a way of thinking that can be incorporated into clinical practice to improve the health and well-being of patients with chronic disease or disability across the continuum of age**." (...) "The overall goal of chronic care is not to cure, but rather to help persons with chronic conditions maintain independence and a high level of functioning. Geriatricians bring special expertise to the management of patients with chronic conditions across multiple sites of care."*

Change in functional performance from baseline to follow-up

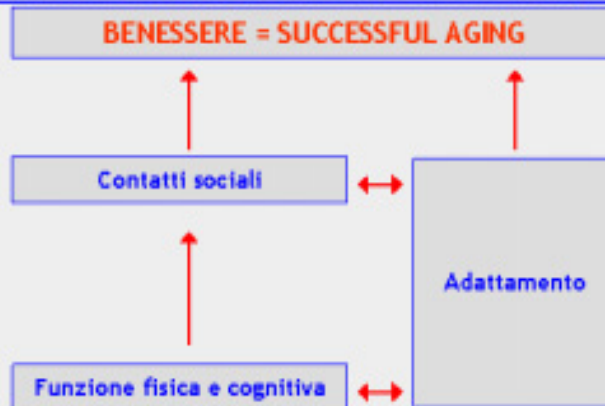

Landi et al. Eur J Neurol
2006; 13:17-23

LA SCELTA IN FUNZIONE DELL'OBIETTIVO

A) *Analisi oggettiva dello stato di salute globale mediante strumenti oggettivi di valutazione multidimensionale*: il 13% degli ultraottantacinquenni raggiunge un punteggio ottimale in tutti i domini indagati.

B) *Percezione soggettiva degli stessi soggetti*: la vecchiaia di successo viene identificata con il senso di benessere derivante dalla possibilità di conciliare/adattare le proprie capacità funzionali alle relazioni sociali. Il 45% degli ultraottantacinquenni - percentuale molto più alta del 13% derivante dall'analisi oggettiva - ritiene di essere in una tale condizione di benessere.

Nell'affrontare i problemi del malato anziano fragile si può essere all'inizio colti da un senso di impotenza. Avendo presenti i successi ottenuti dalla medicina in tutti gli altri campi, può venir da pensare: *“Tanto è vecchio, non vi è nulla da fare!”*

Rendere indipendente un soggetto emiplegico nella propria casa, evitandone l'istituzionalizzazione o impedire le piaghe da decubito in un anziano allettato sono i problemi di tutti i giorni del geriatra; ma sono anche esempi utili per capire il vero significato del “piccolo guadagno” in funzione della qualità della vita.

Se tutto ciò non è servito a convincere il lettore, è bene che egli non diventi mai un geriatra!

Occupational Therapy for Stroke Patients A Systematic Review

Esther M.J. Steultjens, MA; Joost Dekker, PhD; Lex M. Bouter, PhD; Jos C.M. van de Nes, MD;
Edith H.C. Cup, MSc; Cornelia H.M. van den Ende, PhD

Background and Purpose—Occupational therapy (OT) is an important aspect of stroke rehabilitation. The objective of this study was to determine from the available literature whether OT interventions improve outcome for stroke patients.

Methods—An extensive search in MEDLINE, CINAHL, EMBASE, AMED, and SCISEARCH was performed. Studies with controlled and uncontrolled designs were included. Seven intervention categories were distinguished and separately analyzed. If a quantitative approach (meta-analysis) of data analysis was not appropriate, a qualitative approach (best-evidence synthesis), based on the type of design, methodological quality, and significant findings of outcome and/or process measures, was performed.

Results—Thirty-two studies were included in this review, of which 18 were randomized controlled trials. Ten randomized controlled trials had a high methodological quality. For the comprehensive OT intervention, the pooled standardized mean difference for primary activities of daily living (ADL) (0.46; CI, 0.04 to 0.88), extended ADL (0.32; CI, 0.00 to 0.64), and social participation (0.33; CI, 0.03 to 0.62) favored treatment. For the training of skills intervention, some evidence for improvement in primary ADL was found. Insufficient evidence was found to indicate that the provision of splints is effective in decreasing muscle tone.

Conclusions—This review identified small but significant effect sizes for the efficacy of comprehensive OT on primary ADL, extended ADL, and social participation. These results correspond to the outcome of a systematic review of intensified rehabilitation for stroke patients. The amount of evidence with respect to specific interventions, however, is limited. More research is needed to enable evidence-based OT for stroke patients. (*Stroke*, 2003;34:676-687.)

Editorial Comment

Occupational Therapy for Stroke Patients: When, Where, and How?

Technological advances in medicine and increasing longevity in the general population have contributed to the growing number of physically disabled persons in Western countries. Functional impairment following acute illness (eg, stroke) frequently has devastating consequences, and the past several decades have witnessed increasing needs for multidisciplinary rehabilitation interventions. Occupational therapy, an essential part of rehabilitation, offers a wide range of interventions to facilitate independence among disabled patients. In recognition of occupational therapy as a key component in the multidisciplinary rehabilitation of stroke patients, this issue of *Stroke* includes a report from Steultjens and colleagues, who have documented the positive results of comprehensive occupational therapy programs on primary activities of daily living (ADLs), extended ADLs, and social participation of stroke survivors. This systematic review, in conjunction with other scientific evidence, contributes significantly to our pool of knowledge about occupational therapy research, an area that remains poorly studied. Nonetheless, a number of issues related to interventions for patients with impaired physical function following acute illness need to be addressed.

When Is Occupational Therapy Appropriate for Stroke Patients?

The goal of occupational therapy is to restore functional independence, when possible, and to facilitate psychosocial adjustment to residual disability. Unfortunately, criteria for selection of patients who would most benefit from participation in occupational therapy programs have yet to be precisely defined. The heterogeneity of functional and health problems experienced by stroke patients makes it difficult to evaluate multiple outcomes of rehabilitation. Valid negative

predictors of functional recovery after acute events likely include age, urinary incontinence, cognitive impairment, delirium, functional deficits present at admission, and level of social support.^{1,2} Other factors, however, make it difficult to draw definitive conclusions about the efficacy and cost-effectiveness of occupational therapy programs. These include the characteristics of the studied population and of the rehabilitation setting, the types of assessments and/or interventions, and the use of varying outcome measures.

Given the potential conflict between the increasing demand for occupational therapy programs and the development of health care services that limit the availability of rehabilitation beds, identification of stroke patients who could potentially gain improved function from such services is imperative. Although Steultjens and colleagues report a significant effect of occupational therapy on primary and extended ADLs and on social participation, the trials included in their study were very heterogeneous. The characteristics of stroke patients varied significantly, given the types of stroke and acute treatments (ie, in one trial, patients were not admitted to the hospital while in another, they were admitted to the acute stroke unit). The treatments themselves (ie, rehabilitation programs) were not similar to each other: a leisure activity intervention is not the same as an occupational therapy program. The duration of treatment significantly differed (from 30 minutes per week to 1 hour per 5 days a week), and the length of follow-up ranged from 4 weeks to 20 weeks. Furthermore, the current report provides no information concerning the effectiveness of occupational therapy programs in reducing health services use and relative costs for stroke patients. Comprehensive cost-effectiveness analyses and cost-benefit analyses are, therefore, needed to strengthen

Where Is the Appropriate Place to Implement an Occupational Therapy Program?

Despite the growing body of evidence suggesting that improved functional performance after rehabilitation programs may relate to early initiation of treatment,⁴ findings are inconclusive concerning where occupational therapy should take place. Postacute hospital settings, day care programs, home care programs, and skilled nursing facilities are the most frequent settings for current rehabilitation programs that target stroke patients. A changing health care system necessitates that occupational therapy programs focus more on the long-term health needs of disabled persons, helping them to improve functional performance while reducing the health care costs associated with disabilities. It is noteworthy that most trials included in the systematic review of Stultjens and colleagues were conducted as a part of home care programs.

Occupational therapy programs need to be client and family oriented, offering services that range from an institutional setting (ie, postacute hospital) to the community (ie, home care). The occupational therapist may represent the health caregiver who can best provide continuity of care for patients who are being evaluated to join rehabilitation programs, who enter the postacute care hospital, then move back to their homes or to an institutional setting. Therefore, the challenge is to develop occupational therapy programs that improve and/or maintain daily functions of stroke survivors in the community across a continuum of primary and secondary care. A multidisciplinary approach, along with integration of medical, rehabilitative (occupational and physical therapy), and social services into a patient's follow-up care, has already proven to decrease mortality and length of hospital stay, while improving the quality of life in a significant proportion of stroke-dependent patients, including those previously considered to be ineligible for a rehabilitation program.^{1,4,5}

What Is the Best Way to Implement an Occupational Therapy Program?

Stultjens and colleagues note that a major challenge in summarizing the usefulness of occupational therapy relates to the great variability in interventions, which are implemented in very different occupational therapy settings and in numerous countries.⁶ Finally, one should be able to tease out those

Stultjens et al does provide detailed information about the occupational therapy programs utilized in the analyzed trials. Nonetheless, we believe that a more precise understanding of the prognostic value of physical therapy (ie, specific exercise programs), as opposed to occupational therapy interventions or integrated multidisciplinary approaches, warrants future research.

Poststroke occupational therapy programs will have even greater relevance in the future, given the increasing morbidity and longevity in the population. Increased independence in self care and mobility can enhance quality of life and diminish the health care system burden. However, the emerging lack of resources for health care services in industrialized nations and, in particular, the increasingly limited availability of rehabilitation services point to a critical need for evidence-based criteria that would determine which patients stand to benefit the most (in terms of potential for recovery) from specific occupational therapy programs. Further investigations are needed to define which parameters can predict the rehabilitative potential of various types of therapy that focus on physical, psychological, and social approaches, and whether the potential recovery of stroke subjects is influenced by different techniques and/or occupational therapy programs.
